May 14, 2024

 $^1$ Link to paper: <https://arxiv.org/abs/2310.00553>

## Hedging interest rate risk

- <span id="page-1-0"></span>• Many financial institutions have long-term commitments
	- Insurance companies: promise insurance payments
	- Pension funds: promise (defined-benefit) pensions
	- Banks: fund long-term projects with deposits
- Asset-liability management: cover future liabilities by holding sufficient assets
	- Old problem, but still relevant (e.g., collapse of Silicon Valley Bank)
- If market complete, problem trivial by replicating liabilities with zero-coupon bonds (dedication)
- In practice, maturity of liabilities could exceed longest maturity of government bonds, so market incomplete and can only approximate (immunization)

<span id="page-2-0"></span>**[Introduction](#page-1-0)** [Problem statement](#page-6-0) [Robust immunization](#page-13-0) [Evaluation](#page-27-0) [Conclusion](#page-37-0)<br>
Robust immunization Evaluation Conclusion 

## Bond price and duration

- Consider cash flows  $f_1, \ldots, f_N$  paid out at time  $t_1, \ldots, t_N$
- Assuming constant interest rate  $r$ , present value is

$$
P = \sum_{n=1}^{N} e^{-rt_n} f_n
$$

• Interest rate sensitivity of bond price is

$$
D := -\frac{\partial \log P}{\partial r} = -\frac{1}{P} \frac{\partial P}{\partial r} = \frac{1}{P} \sum_{n=1}^{N} t_n e^{-rt_n} f_n
$$

•  $D$  is called duration because it is weighted average of time to payment:  $D = \sum_{n=1}^{N} w_n t_n$  for  $w_n := e^{-rt_n} f_n / P$ , with  $\sum w_n = 1$ 

KO K (FE K E K E K AR)

<span id="page-3-0"></span>**[Introduction](#page-1-0)** [Problem statement](#page-6-0) [Robust immunization](#page-13-0) [Evaluation](#page-27-0) [Conclusion](#page-37-0)<br>
Robust immunization Evaluation Conclusion 

## Classical immunization

<span id="page-3-1"></span>• Interest rate need not be constant; if  $y(t)$  denote (pure) yield at term t, bond price and duration are

$$
P = \sum_{n=1}^{N} e^{-y(t_n)t_n} f_n,
$$
  

$$
D = \frac{1}{P} \sum_{n=1}^{N} t_n e^{-y(t_n)t_n} f_n
$$

- Here duration is sensitivity of bond price with respect to parallel shift in yield curve  $\rightarrow$  [Example](#page-40-0)
- Classical immunization prescribes to match duration of asset and liability so that equity (asset minus liability) is insensitive to yield curve shifts (Macaulay, [1938;](#page-38-0) Samuelson, [1945;](#page-39-0) Redington, [1952\)](#page-39-1) KOD KAR KED KED EE AAA

<span id="page-4-0"></span>

## Limitations of classical immunization

- By construction, only allows for parallel shifts to yield curve, but in practice yield curve can change in many ways
- Because duration is only a scalar, when there are many bonds, it is not obvious how to choose portfolio (indeterminacy)
- Generalizations have been proposed, for instance matching convexity (high-order duration)

$$
\frac{1}{P}\sum_{n=1}^N t_n^2 e^{-y(t_n)t_n} f_n,
$$

but it has been found to lead to portfolio instability and poor performance

• Many other ad hoc methods but lack of principle

<span id="page-5-0"></span>**[Introduction](#page-1-0)** [Problem statement](#page-6-0) [Robust immunization](#page-13-0) [Evaluation](#page-27-0) [Conclusion](#page-37-0)<br>

KOD KAR KED KED EE AAA

# This paper

- Propose new robust immunization method that maximizes equity against arbitrary interest rate shock
- Idea: span perturbations to yield curve by basis functions, and optimize against worst case perturbation
- Tools:
	- functional analysis: Gateaux derivative
	- numerical analysis: Chebyshev polynomials
- Excellent performance in static and dynamic hedging experiments

<span id="page-6-0"></span>

## Model

- Continuous time,  $t \in [0, T]$
- *J* available bonds for trade; bond *i's* cumulative payout denoted by weakly increasing  $\mathit{F}_j: [0,\, \mathcal{T}] \rightarrow \mathbb{R}_+$ 
	- If zero-coupon bond with face value 1 and maturity  $t_j$ , then

$$
F_j(t) = \begin{cases} 0 & \text{if } 0 \leq t < t_j, \\ 1 & \text{if } t_j \leq t \leq T \end{cases}
$$

• If continuously pay out coupon  $c_j$ , then  $F_j(t) = c_j t$ 

- $F : [0, T] \rightarrow \mathbb{R}_+$ : cumulative cash flow to be immunized
- $v : [0, T] \rightarrow \mathbb{R}$ : yield curve
- Present value of liability is Riemann-Stieltjes integral

$$
\int_0^T e^{-ty(t)} dF(t)
$$

KED KAR KED KED EE OQO

<span id="page-7-0"></span>

## Cumulative discount rate

- Convenient to define "cumulative discount rate"  $x(t) := ty(t)$
- By definition of forward rate, we have

$$
x(t)=\int_0^t f(u)\, \mathrm{d} u,
$$

where  $f(u)$  is instantaneous forward rate at term u

• Present value of asset/liability becomes functional

$$
P(x) := \int_0^T e^{-x(t)} dF(t),
$$

• Fund manager's problem is to choose bond portfolio  $z=(z_j)\in\mathbb{R}^{J}$  to approximate  $P(x)$  by  $\sum_{j=1}^{J}z_jP_j(x)$  in some optimal way

## Robust immunization problem

- <span id="page-8-0"></span> $\bullet \; \mathcal{Z} \subset \mathbb{R}^J$ : set of admissible portfolios
- $\mathcal{H}$ : set of admissible perturbations to cumulative discount rate
- After perturbation  $h \in \mathcal{H}$ , portfolio value ("asset") is

$$
V(z,x+h):=\sum_{j=1}^J z_jP_j(x+h)
$$

• Hence asset minus liability ("equity") is

$$
E(z, x+h) := V(z, x+h) - P(x+h)
$$

• Fund manager seeks to maximize worst case equity, so solve

$$
\sup_{z\in\mathcal{Z}}\inf_{h\in\mathcal{H}}E(z,x+h)
$$

<span id="page-9-0"></span>

## **Assumptions**

#### Assumption (Discrete payouts)

The bonds and liability pay out on finitely many dates, whose union is denoted by  $\{t_n\}_{n=1}^N \subset (0, T]$ .

#### Assumption (Portfolio constraint)

The set of admissible portfolios  $\mathcal{Z} \subset \mathbb{R}^J$  is nonempty and closed. Furthermore, all  $z \in \mathcal{Z}$  satisfy value matching:

$$
P(x) = \sum_{j=1}^{J} z_j P_j(x).
$$

• Merely a normalization (objective function  $= 0$  at  $h = 0$ )

<span id="page-10-0"></span>

## Space of cumulative discount rates

- Let  $C^r[0, T]$  be vector space of r-times continuously differentiable functions on  $[0, T]$
- Space of forward rates is  $C[0, T]$  endowed with supremum norm  $\left\Vert f\right\Vert _{\infty}=\sup_{t\in\left[0,\mathcal{T}\right]}\left|f(t)\right|$
- Since cumulative discount rate is integral of forward rate,  $x(t) = \int_0^t f(u) \, \mathrm{d}u$ , let

$$
\mathcal{X}=\left\{x\in C^1[0,T]:x(0)=0\right\}
$$

 $\bullet$   ${\mathcal X}$  is Banach space with norm  $\left\| x \right\|_{{\mathcal X}} = \sup_{t \in [0,T]} \left| x'(t) \right|$ 

KOD KARD KED KED EN MAG

<span id="page-11-0"></span>

## **Assumption**

#### Assumption (Basis)

There exists a countable basis  $\{h_i\}_{i=1}^{\infty}$  of X such that for each  $I \in \{1, \ldots, N\}$ , the  $I \times N$  matrices  $H = (h_i(t_n))$  and  $G = (h_i'(t_n))$ have full row rank.

- This assumption allows us to
	- approximate any  $x \in \mathcal{X}$  by finitely many basis functions, and
	- avoid indeterminacy
- Example: if  $h_i$  polynomial of degree *i* with  $h_i(0) = 0$ , then OK by Stone-Weierstraß theorem
- Intuitively,  $H(G)$  is matrix of perturbations to cumulative discount rate (forward rate) evaluated at payout dates

<span id="page-12-0"></span>

## Admissible perturbations

• To operationalize, define set of admissible perturbations by

$$
\mathcal{H}_{I}(\Delta)\coloneqq\left\{h\in\text{span}\left\{h_{i}\right\}_{i=1}^{I}:\left(\forall n\right)\left|h'\right(t_{n}\right)\right|\le\Delta\right\}
$$

- Intuition: perturb forward rate by at most  $\pm\Delta$  within span of first I basis functions
- Thus final maxmin problem is

$$
\sup_{z\in\mathcal{Z}}\inf_{h\in\mathcal{H}_l(\Delta)}E(z,x+h)
$$

• Note: setting in classical immunization corresponds to  $I = 1$ and  $h_1(t) = t$  (hence  $h'_1(t) = 1$ )

<span id="page-13-0"></span>[Introduction](#page-1-0) [Problem statement](#page-6-0) **[Robust immunization](#page-13-0)** [Evaluation](#page-27-0) [Conclusion](#page-37-0)<br>00000 0000000 0000000 **COOOO** COOOOO O

## Gateaux and Fréchet derivatives

• For perturbation  $h \in \mathcal{X}$ , rate of change in liability value is Gateaux derivative

$$
\delta P(x; h) := \lim_{\alpha \to 0} \frac{1}{\alpha} (P(x + \alpha h) - P(x))
$$

$$
= -\int_0^T e^{-x(t)} h(t) dF(t)
$$

• Can define bounded linear operator  $P'(x)$  by

$$
P'(x)h = -\int_0^T e^{-x(t)}h(t)\,\mathrm{d}F(t),
$$

called Fréchet derivative

<span id="page-14-0"></span>[Introduction](#page-1-0) [Problem statement](#page-6-0) **[Robust immunization](#page-13-0)** [Evaluation](#page-27-0) [Conclusion](#page-37-0)<br>00000 0000000 000000 0**00000** 000000 00000 0

Sensitivity matrix/vector

 $\bullet\,$  Define sensitivity matrix  $A=(a_{ij})\in\mathbb{R}^{I\times J}$  and vector  $b=(b_i)\in\mathbb{R}^I$  with respect to basis functions by

$$
a_{ij} := -\frac{\delta P_j(x; h_i)}{P(x)} = \frac{1}{P(x)} \int_0^T e^{-x(t)} h_i(t) dF_j(t),
$$
  

$$
b_i := -\frac{\delta P(x; h_i)}{P(x)} = \frac{1}{P(x)} \int_0^T e^{-x(t)} h_i(t) dF(t)
$$

• Note:  $b_i$  is duration if  $h_i(t) = t$ 

 $\bullet$  Convenient to define  $A_+ \in \mathbb{R}^{(I+1) \times J}$  and  $b_+ \in \mathbb{R}^{I+1}$  by

$$
A_+ \coloneqq \begin{bmatrix} a_0 \\ A \end{bmatrix} \quad \text{and} \quad b_+ \coloneqq \begin{bmatrix} b_0 \\ b \end{bmatrix},
$$

where  $a_{0j},\ b_0=1$  defined analogously using  $h_0(t)\equiv 1$ KO K (FE K E K E K AR)

<span id="page-15-0"></span>

[Introduction](#page-1-0) [Problem statement](#page-6-0) **[Robust immunization](#page-13-0)** [Evaluation](#page-27-0) [Conclusion](#page-37-0)<br>
000000 00000000 0000000 00**00000** 000000 000000 000000 0

## Sensitivity of equity

• Recall definition of equity

$$
E(z,x):=\sum_{j=1}^J z_jP_j(x)-P(x)
$$

• If perturbation is  $h = \Delta \sum_{i=1}^{I} w_i h_i \in \mathcal{H}_I(\Delta)$ , sensitivity of equity becomes

$$
\lim_{\Delta \to 0} \frac{1}{\Delta P(x)} E(z, x + h) = -\langle w, Az - b \rangle
$$

• For  $h \in \mathcal{H}_I(\Delta)$ , coefficients  $w = (w_i)$  need to satisfy certain restrictions

<span id="page-16-0"></span>

## Auxiliary problem

• Straightforward to show  $h = \Delta \sum_{i=1}^{I} w_i h_i \in \mathcal{H}_I(\Delta)$  if and only if

$$
\mathcal{W} \coloneqq \left\{ w \in \mathbb{R}^l : G'w \in [-1,1]^N \right\},\
$$

where  $G = (h'_i(t_n)) \in \mathbb{R}^{I \times N}$ 

• This motivates solving auxiliary problem

$$
\sup_{z\in\mathcal{Z}}\inf_{w\in\mathcal{W}}-\langle w,Az-b\rangle\iff\inf_{z\in\mathcal{Z}}\sup_{w\in\mathcal{W}}\langle w,Az-b\rangle
$$

to solve maxmin problem

$$
\sup_{z\in\mathcal{Z}}\inf_{h\in\mathcal{H}_l(\Delta)}E(z,x+h)
$$

KOD KARD KED KED EN MAG

<span id="page-17-0"></span>

## Solution to auxiliary problem

#### Proposition (Minmax)

Suppose Assumptions hold,  $I \geq J-1$ , and sensitivity matrix  $A_+$ has full column rank. Then

1. There exists  $(z^*, w^*) \in \mathcal{Z} \times \mathcal{W}$  that achieves minmax value

$$
V_I(\mathcal{Z}) \coloneqq \inf_{z \in \mathcal{Z}} \sup_{w \in \mathcal{W}} \langle w, Az - b \rangle.
$$

2.  $V_1(\mathcal{Z}) \geq 0$ , and  $z \in \mathcal{Z}$  achieves  $V_1(\mathcal{Z}) = 0$  if and only if  $A_{+}z = b_{+}$ .

<span id="page-18-0"></span>

### Robust immunization

#### Theorem (Robust immunization)

1. Guaranteed equity satisfies

$$
\lim_{\Delta\downarrow 0}\frac{1}{\Delta}\sup_{z\in\mathcal{Z}}\inf_{h\in\mathcal{H}_1(\Delta)}E(z,x+h)=-P(x)V_1(\mathcal{Z}).
$$

2. Letting  $z^* \in \mathcal{Z}$  be solution to auxiliary problem and  $\theta_j\coloneqq z_j P_j(\mathsf{x})/P(\mathsf{x})$  be corresponding portfolio share, then

$$
\sup_{h\in\mathcal{H}_I(\Delta)}|E(z^*,x+h)|\leq \Delta P(x)\left(V_I(\mathcal{Z})+\frac{1}{4}\Delta\,T^2\mathrm{e}^{\Delta\,T}(1+\|\theta\|_1)\right).
$$

● Solution z<sup>\*</sup> to auxiliary problem achieves guaranteed equity in limit  $\Delta \downarrow 0$ 

20/38

KOD KARD KED KED EN MAG

## Implementation

- Implementation requires choice of basis functions  $\{h_i\}_{i=1}^\infty$  $i=1$
- Natural to use (Chebyshev) polynomials because Assumptions satisfied and good approximation property (Trefethen, [2019\)](#page-39-2)
- Let  $T_n : [-1, 1] \to \mathbb{R}$  be Chebyshev polynomial defined by  $T_n(\cos\theta) = \cos n\theta$
- Map  $[-1, 1]$  to  $[0, 7]$  by affine transformation, so let  $g_i(t) = T_{i-1}(2t/T - 1)$  be basis for forward rate
- Define basis for cumulative discount rate by

$$
h_i(t) = \int_0^t g_i(u) \, \mathrm{d} u
$$

## Basis for cumulative discount rate

## How good is forward rate approximation?

- Use 1985–2022 daily yield curve data from Gürkaynak et al. [\(2007\)](#page-38-1), who estimate Svensson [\(1994\)](#page-39-3) model
- For each day s and term  $t_n = n/12$  ( $n = 1, \ldots, 360$ ), calculate the d-day ahead forward rate change  $f_{s+d}(t_n) - f_s(t_n)$
- For each s and  $d = 1, \ldots, 100$ , run OLS regression

$$
f_{s+d}(t_n)-f_s(t_n)=\sum_{i=1}^l\gamma_{isd}g_i(t_n)+\epsilon_s(t_n),\quad n=1,\ldots,N
$$

• Calculate goodness-of-fit measure

$$
R_d^2 := \frac{\sum_{s=1}^{S} \sum_{n=1}^{N} \left( \sum_{i=1}^{I} \hat{\gamma}_{isd} g_i(t_n) \right)^2}{\sum_{s=1}^{S} \sum_{n=1}^{N} (f_{s+d}(t_n) - f_s(t_n))^2}
$$

KOD KARD KED KED EN MAG

### Goodness-of-fit

### Goodness-of-fit

## Implementing robust immunization

1. Let

- $\mathbf{t} = (t_1, \ldots, t_N)$  be  $1 \times N$  vector of asset/liability payout dates
- $\mathbf{v} = (v_1, \ldots, v_N)$  be  $1 \times N$  vector of yields
- $f = (f_1, \ldots, f_N)$  be  $1 \times N$  vector of liabilities
- $\mathbf{F} = (f_{in})$  be  $J \times N$  matrix of bond payouts
- 2. Let  $I \geq J 1$ , define basis functions  $\{h_i\}$  as above, construct matrices of
	- basis functions  $\mathbf{H} = (h_i(t_n)) \in \mathbb{R}^{I \times N}$ ,
	- derivatives  $\mathbf{G} = (h'_{i}(t_{n})) = (g_{i}(t_{n})) \in \mathbb{R}^{I \times N}$ ,
	- $\bullet$  zero-coupon bond prices  $\mathbf{p} = \exp(-\mathbf{y} \odot \mathbf{t}) \in \mathbb{R}^{1 \times N}$
- 3. Define sensitivity matrix/vectors by

 $A := (\mathbf{H} \text{ diag}(\mathbf{p})\mathbf{F}')/(\mathbf{p}\mathbf{f}'),$  $b \coloneqq \mathbf{H} \text{ diag}(\mathbf{p}) \mathbf{f}'/(\mathbf{p} \mathbf{f}')$

## Yield curve and parallel shift [Return](#page-3-1)

<span id="page-41-0"></span>

#### <span id="page-42-0"></span>[References](#page-38-4)

## Robust immunization with principal components

- Suppose perturbations to forward rates have factor structure
	- E.g., parallel shift is dominant
- For  $\Delta_1 \gg \Delta_2 > 0$ , consider set of admissible perturbations

$$
\mathcal{H}_1(\Delta_1, \Delta_2)
$$
  
 := { $h : (\exists \alpha)(\forall n) | \alpha h'_1(t_n) | \leq \Delta_1, |h'(t_n) - \alpha h'_1(t_n)| \leq \Delta_2$ }

• Idea:

- First, perturb forward rate in direction  $h'_1$  by magnitude at most  $\Delta_1$ ,
- Then perturb in arbitrary direction by magnitude at most  $\Delta_2$

## <span id="page-43-1"></span>Robust immunization with principal components

<span id="page-43-0"></span>Theorem Suppose the set

$$
\mathcal{Z}_1 \coloneqq \left\{ z \in \mathcal{Z} : \sum_{j=1}^J a_{1j} z_j = b_1 \right\}
$$

is nonempty. Then guaranteed equity satisfies

$$
\lim \frac{1}{\Delta_2} \sup_{z \in \mathcal{Z}} \inf_{h \in \mathcal{H}_1(\Delta_1, \Delta_2)} E(z, x + h) = -P(x) V_1(\mathcal{Z}_1),
$$

where the limit is taken over  $\Delta_1, \Delta_2 \rightarrow 0$ ,  $\Delta_1/\Delta_2 \rightarrow \infty$ , and  $\Delta_1^2/\Delta_2 \rightarrow 0$  .
